ABSTRACT

Chromosome numbers previously have been reported for 50 individuals of *Symphyotrichum dumosum* and 5 individuals of *S. simmondsii*. In addition, 95 new reports for *S. dumosum* to variety and 19 new reports for *S. simmondsii* bring the total number of counts to 169, covering most of the geographical ranges of the two species. Cytogeography maps are presented for both species.

In total, 50 chromosome number counts have been reported previously (Appendix 1) for *Symphyotrichum dumosum* (L.) Nesom and 5 counts for *S. simmondsii* (Small) Nesom, mostly under the names *Aster dumosus* L. and *Aster simmondsii* Small. Twenty-four diploid counts ($2n=8_{II}$, $2n=16$) were reported for *Aster dumosus* by Jones (1980), Semple & Brouillet (1980), Semple (1985), Semple and Chmielewski (1987), Semple et al. (1989, 1992, 1993) and Semple and Cook (2004). Eleven tetraploid counts ($2n=16_{II}$, $2n=32$) were reported for *A. dumosus* by Jones (1980), Semple and Brouillet (1980), Semple (1985), Semple et al. (1989, 2003), and Semple and Cook (2004). One count of $2n=16$ was reported for *S. dumosum* cult. var. “Pink Cloud” by Semple et al. (2015).

Five octoploid counts ($2n=32_{II}$, $2n=64$) were reported for *Symphyotrichum simmondsii* by Turner (1978, as *Aster purpuratus*, $n=ca$ 30 pairs), Semple et al. (1983), Semple (1985), and Semple and Cook (2004). The cytogeographies of the two species have not been presented previously.

Semple (2024) has reviewed the nomenclature of the *Symphyotrichum dumosum* complex and accepted four varieties within *S. dumosum*; *Symphyotrichum dumosum* var. *coridifolium* (Michx.) Semple, M. Horsburgh, and M. Haggitt, var. *dumosum*, var. *strictior* (Torr. & Gray) Nesom, and var. *subulifolium* (Torr. & Gray) Nesom. Semple et al. (2024) discussed morphological features of the four varieties investigated in a multivariate analysis. Ray floret color and orientation of mid stem, upper stem and branch leaves were found useful in assigning most individuals to a variety.

MATERIALS AND METHODS

Meiotic counts were made from pollen mother cells (PMCs) dissected from buds fixed in the field in 3:1 ethanol (EtOH): glacial acetic acid for a minimum of 24 hours under refrigeration and subsequently stored under refrigeration in 70% EtOH. Mitotic counts were made from root tip cells taken from transplanted wild rootstocks or from seedlings grown from achenes collected in the wild. Root tips were pretreated in 0.01% colchicine or saturated paradichlorobenzene for 2–3 hours, fixed in either Modified Carnoy’s Fixative (4:3:1 chloroform:EtOH:glacial acetic acid) or Acetic Alcohol Fixative (3:1 EtOH:glacial acetic acid) for a minimum of 24 hours under refrigeration and hydrolyzed in 1N HCl for 30 min at 60°C before squashing. Anther sacs containing PMCs and meristematic root tips were squashed in 1% acetic orcein and counts of chromosomes were made from freshly prepared material.

Vouchers for all previously unpublished counts were deposited in WAT in MT (or will be and are currently in the possession of the first author). Identifications were reconfirmed for this study by the first author either from collections in WAT in MT or on hand in Waterloo, and from digital images taken by the first author, from images available online through SERNEC (2022), and from digital images provided by the staff of the herbarium at the Jardin botanique (MT) in Montréal, Québec.

RESULTS AND DISCUSSION

Identifications of the vouchers for 50 previously reported chromosome counts for specimens of *Symphyotrichum dumosum* and 5 previously reported counts for specimens *S. simmondsii* were confirmed and are listed to variety in Appendix 1. In total, 95 previously unreported chromosome counts for individuals of *S. dumosum* and 19 previously unreported counts for *S. simmondsii* are listed to variety in Appendix 2. In total, 169 counts are now known for *S. dumosum* and *S. simmondsii*. The first reports for counts for *S. dumosum* were by Jones (1980; $2n=7_{II}+2_I+$ frags., $2n=8_{II}$, $2n=8_{II}+1B$ super. or frags., and $2n=16_{II}$) and Semple and Brouillet (1980; $2n=8_{II}$ and $2n=16$) with subsequent reports to species by Semple (1985), Semple & Chmielewski (1987), Semple, Chmielewski and Lane (1989), Semple, Chmielewski and Xiang (1992), Semple, Zhang and Xiang (1993), Semple and Cook (2004), and Semple, et al. (2015). The first report for *S. simmondsii* was reported by Turner (1978) as $2n=cf.c.30_{II}$ from Dade Co., Florida (*Pleittman & Turner F-26 FTG!*) as *Aster purpuratus* Nees with subsequent counts by Semple (1985) for *S. simmondsii* ($2n=32_{II}$ as *Aster simmondsii*) and $2n=64$ by Semple, Chmielewski and Chinnappa (1983 as *Aster simmondsii*), and Semple and Cook (2004 as *Symphyotrichum simmondsii*).

The cytogeography of *Symphyotrichum dumosum* is shown in Fig. 1. The ranges of the four varieties recognized here are also shown in Fig. 1 and are based on a large number of collections seen in person or via SERNEC. The var. *dumosum* and the var. *strictior* (Torr. & A. Gray) Nesom are northern in distribution and are nearly allopatric with overlaps in ranges in southeastern Missouri and possibly western Pennsylvania. All collections from New England, southeastern New York, eastern Pennsylvania and Delaware were determined to belong in var. *dumosum* which occurs at both diploid and tetraploid levels. All collections observed from Wisconsin, Michigan, and Ontario were determined to belong in var. *strictior*, which is only known at the tetraploid level. All collections of var. *coridifolium* came from Pennsylvania south to central Florida west to southern Missouri and south to eastern Texas with diploids and tetraploids occurring over the entire range of the variety. All collections of var. *subulifolium* came from southeastern North Carolina south to southern Florida on the coastal plain and west to eastern Texas and north to southern Oklahoma and adjacent Arkansas with considerable overlap with the southern range of var. *coridifolium*. Diploids and tetraploids occurred throughout much of the range of var. *subulifolium* but sampling was sparse in the western portions of the range. Intermediates between the two southern varieties were sampled in areas of sympatry with a diploid sampled in South Carolina and tetraploids sampled in South Carolina, Georgia, Florida and Louisiana.

The cytogeography of *Symphyotrichum simmondsii* is shown in Figure 2. The species occurs on the coastal plain from northeastern North Carolina to southern Florida with the range extending across Florida panhandle to Dauphin Island, Alabama. All counts were octoploid in North Carolina, South Carolina, and Florida. No counts are known for plants from Georgia and Alabama.

ACKNOWLEDGEMENTS

This research was supported by Natural Sciences and Engineering Research Council of Canada Operating and Discovery Grants to J.C.S. The following people are thanked for assistance in the field: Luc Brouillet, Judith Canne-Hilliker, Rachel Cook, Bruce Currie, Brenda Semple, and Alan Weakley.

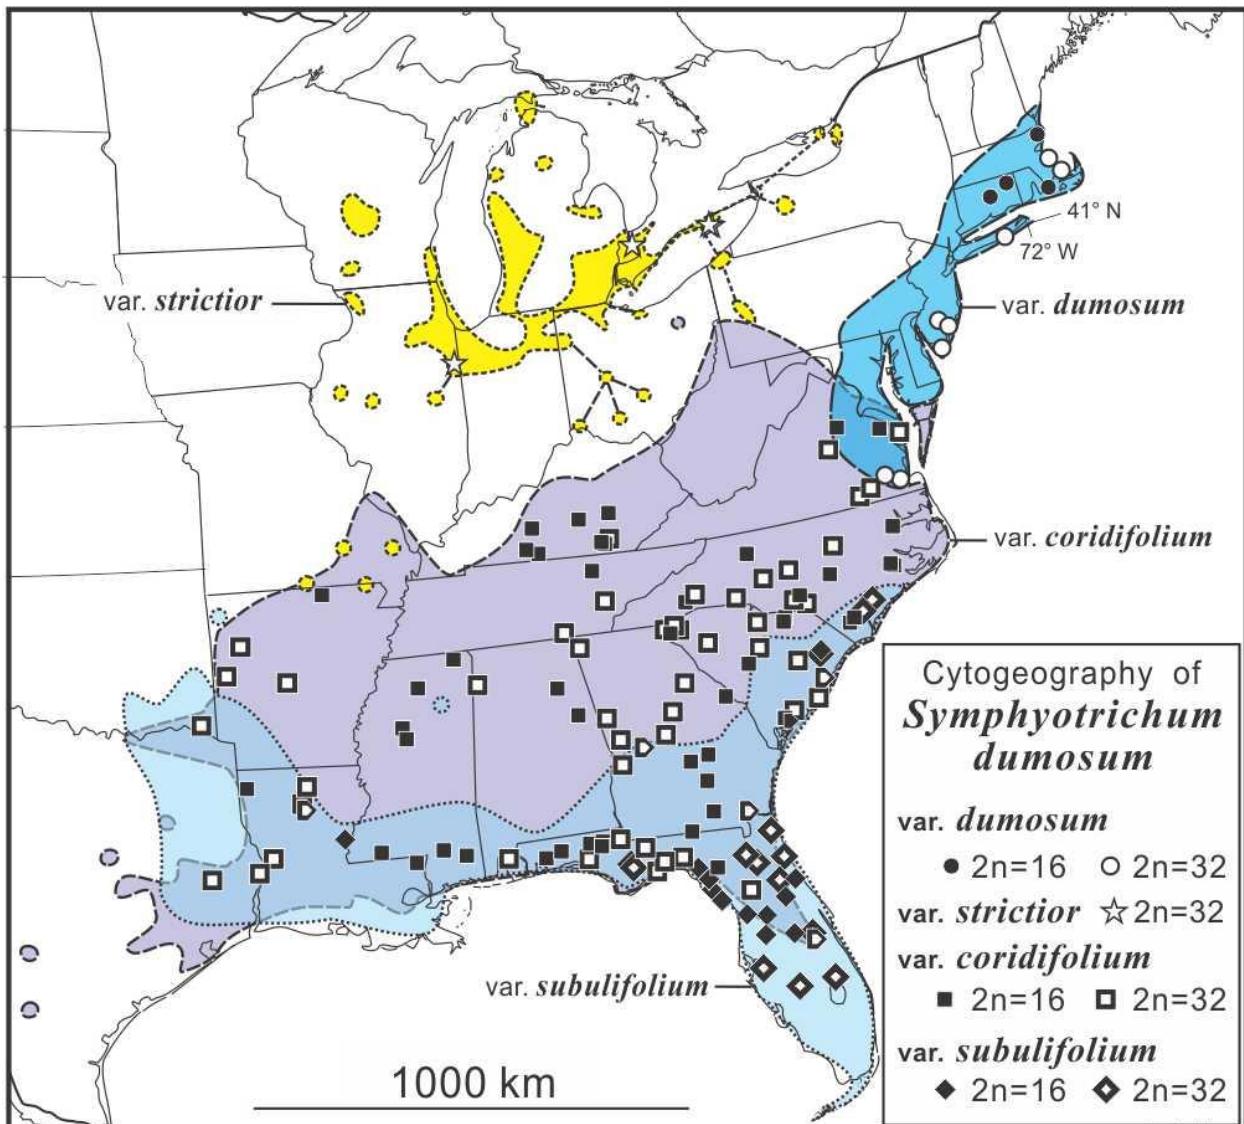

Figure 1. Distribution of cytotypes of *Symphyotrichum dumosum*: var. *dumosum* (2x black dots, 4x solid white circles); var. *strictior* (4x solid white stars); var. *coridifolium* (2x black squares, 4x white with thick black outline); var. *subulifolium* (2x black diamonds, 4x white diamonds with thick black outline); hybrid symbols indicate plants that are likely varietal intermediates. The colored ranges of the four varieties are indicated in broken-lines and are based on all herbarium specimens examined and reports in the literature.

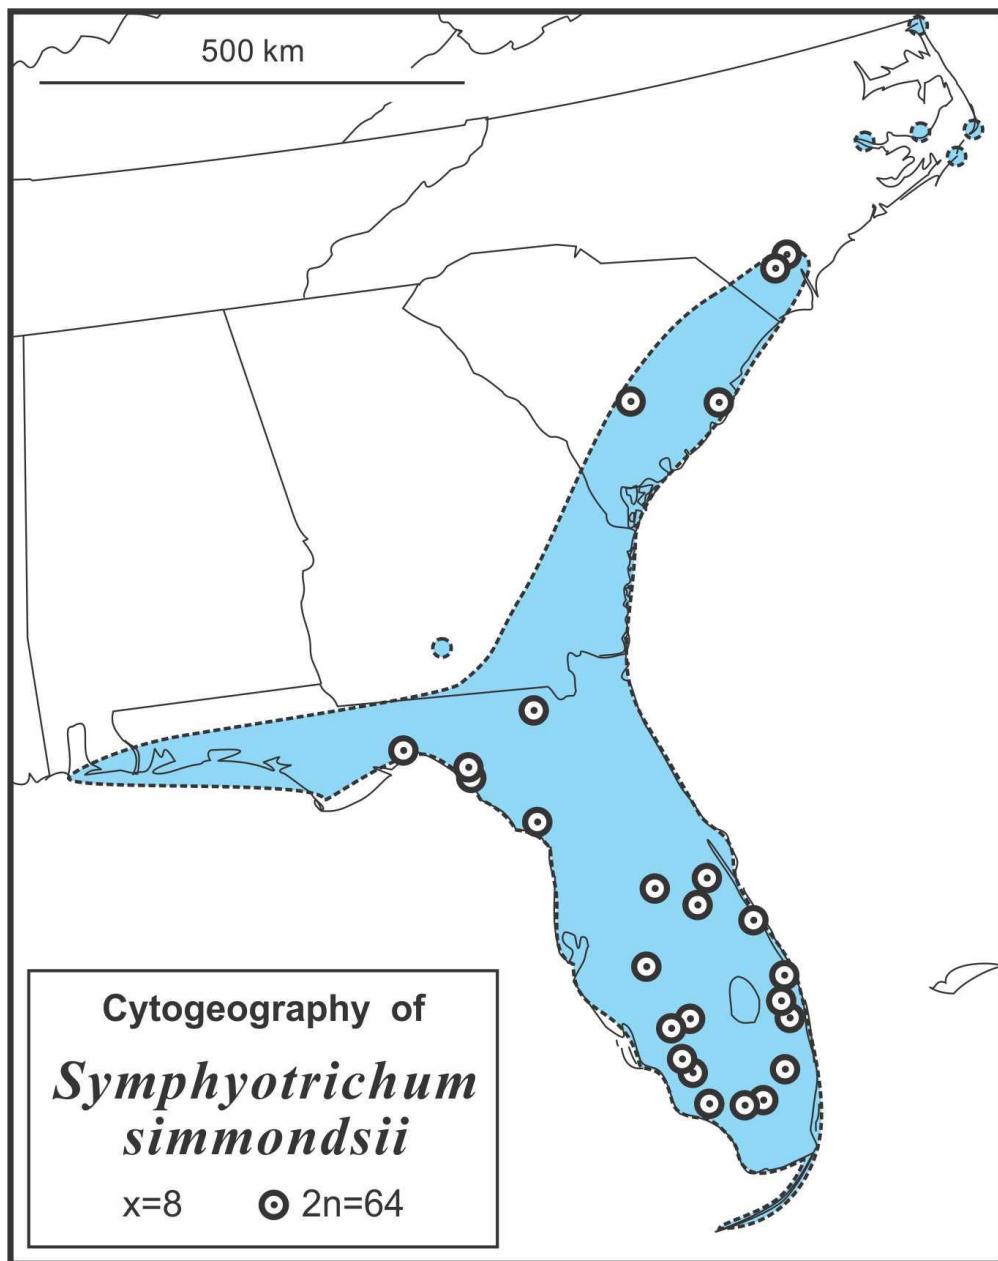

Figure 2. Distribution of cytotypes of *Symphyotrichum simmondsii*: octoploids 8x, circles with dot; range based on all collections seen and literature.
